Overview

Overview of observations and primary results

Results give rise to two complimentary questions:

- Is there a chromospheric footprint to the solar wind?
- Does the chromosphere have heliospheric “impact”?

“Looking” to the future....

Observations & Early Results

The TRACE Inter-Network Oscillation (INO) program was designed to study the interplay of the chromospheric magnetic environment and the ubiquitous 5 minute oscillations.

Waves are significantly modified by the expanding magnetic “canopy”, where $\rho_{\text{plasma}} \beta = 1$ and by the partitioning of the environment into **open** and **closed** regions.

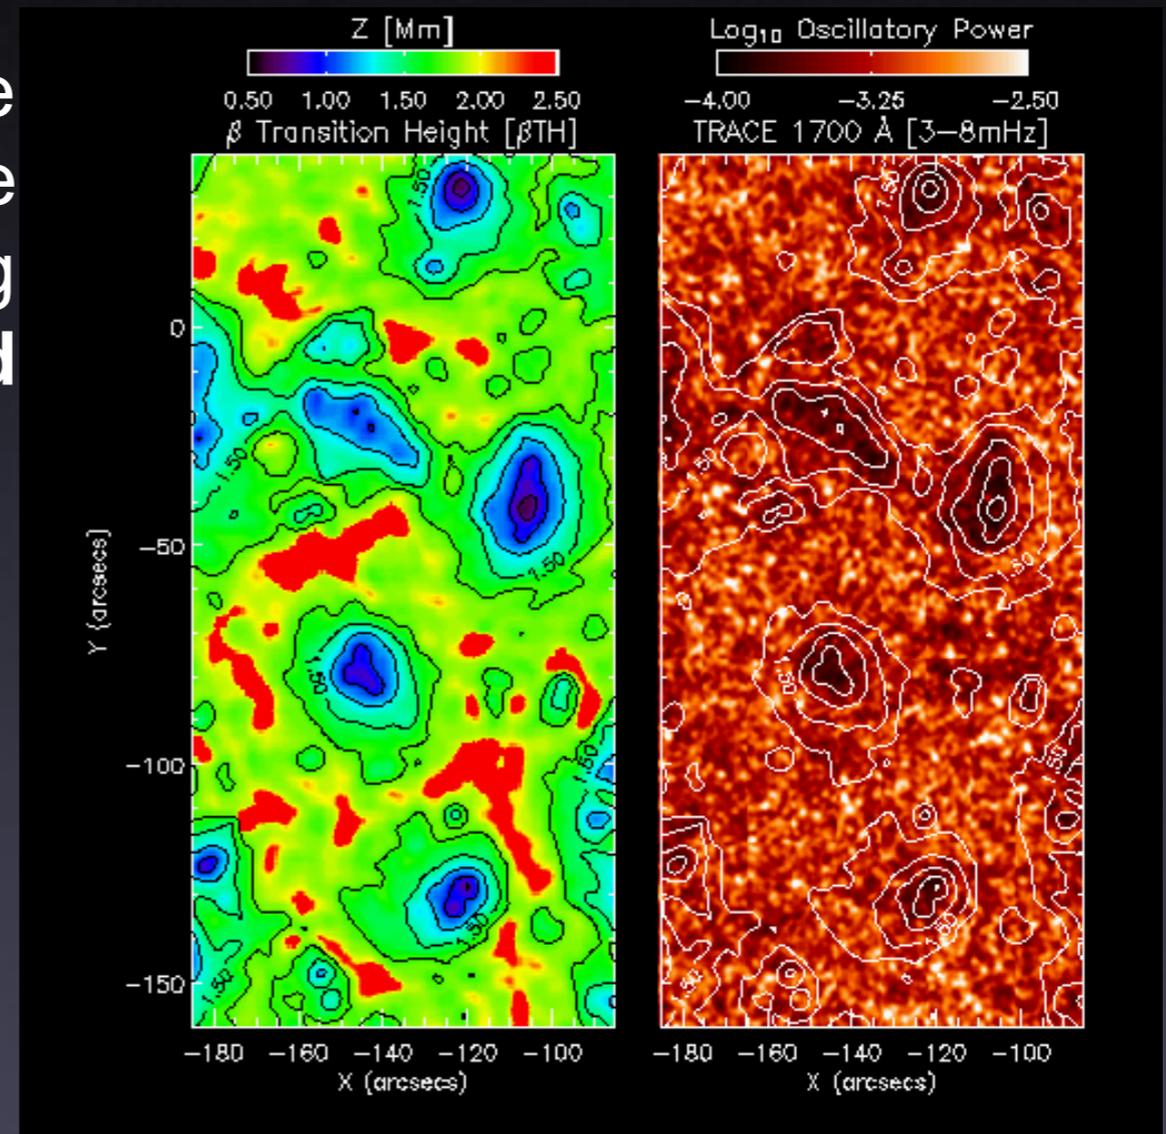

Observe changes in:

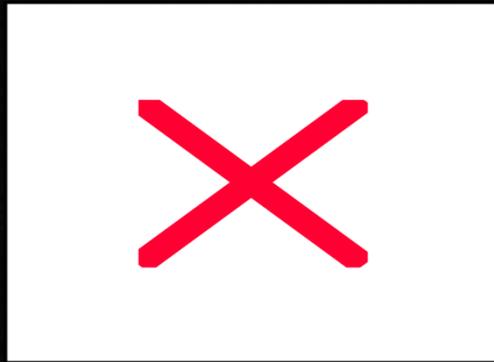

Frequency

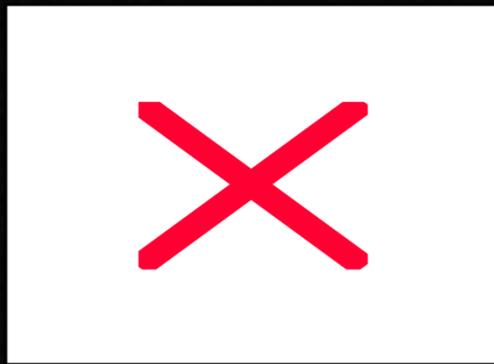

Power

Phase/“Travel-Time”

Travel-time studies are direct measures of the plasma topography; our focus for the remainder.

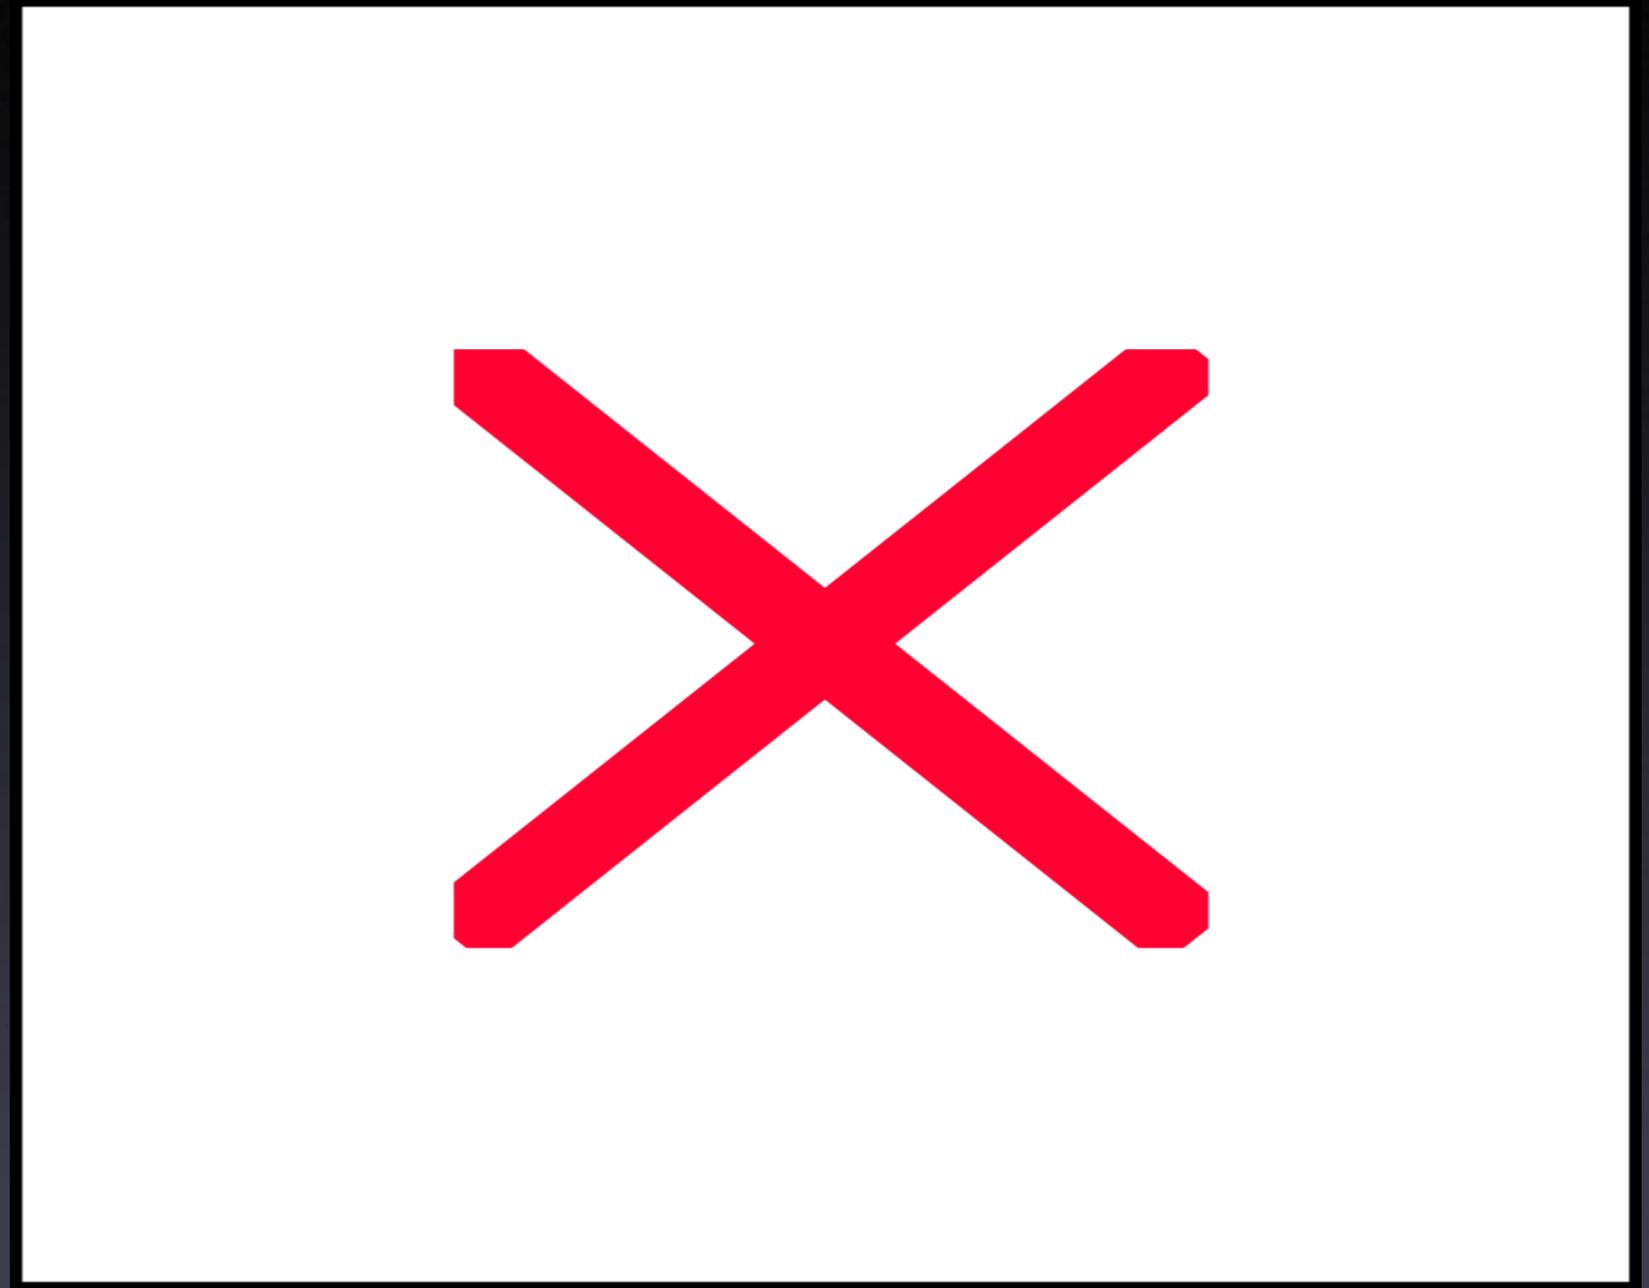

TRACE Sample

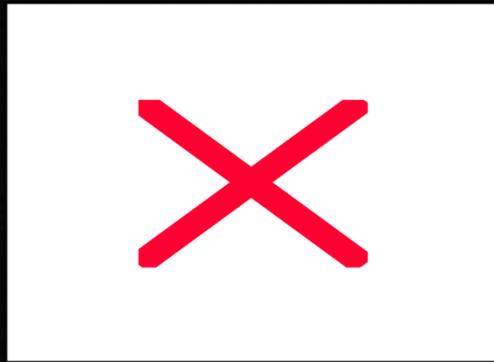

July 14 2003
TRACE 1600Å
Duration 78 mins.
Cadence 12s
0.5"x0.5" Pixels

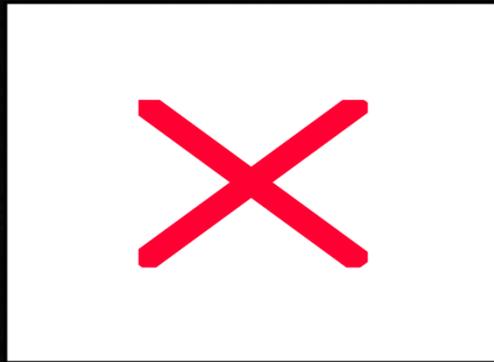

Pixel-scale travel-times of ~8-10s expected in the QS between the TRACE continua.

256 arcseconds

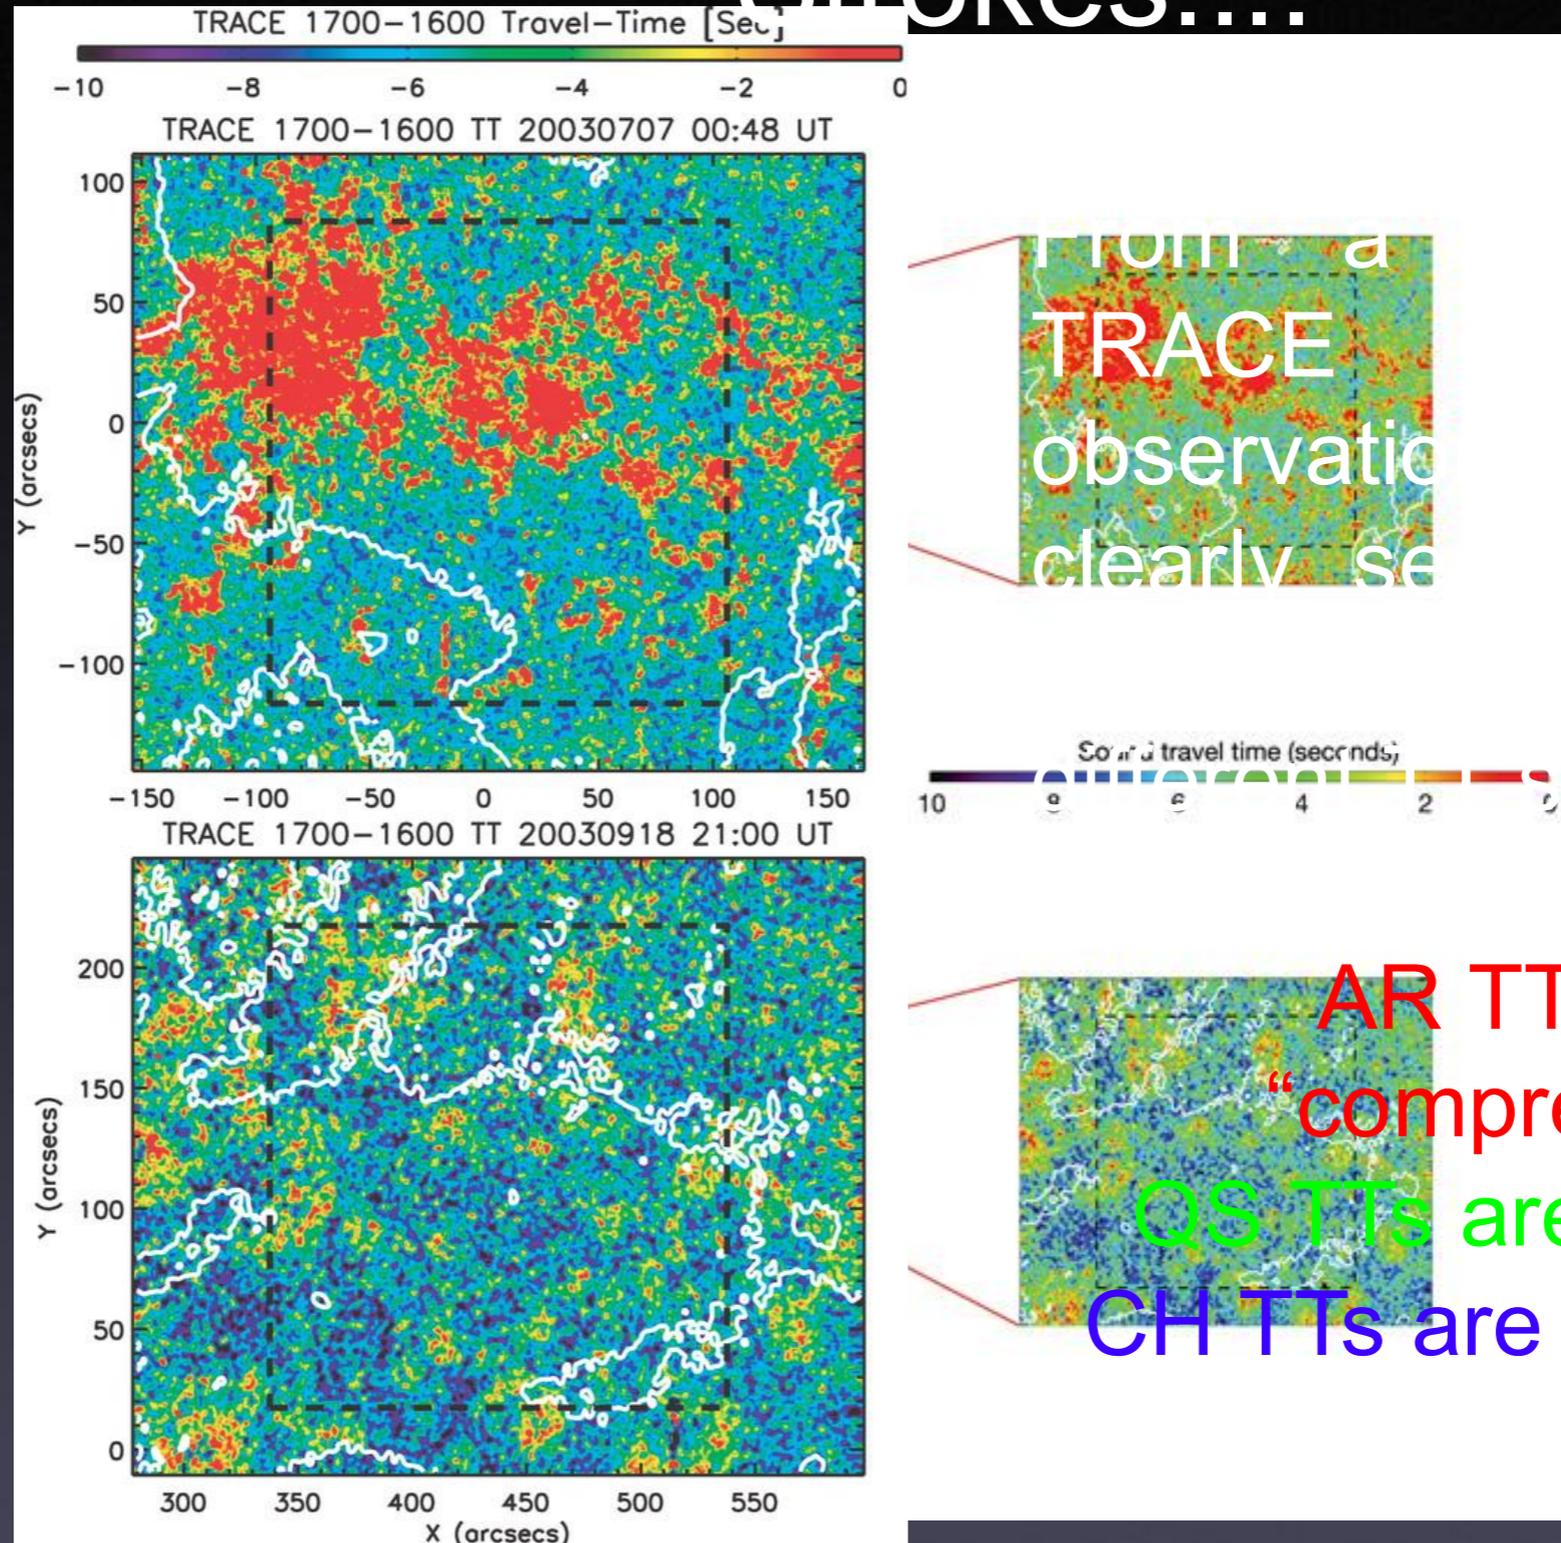

340 arcseconds

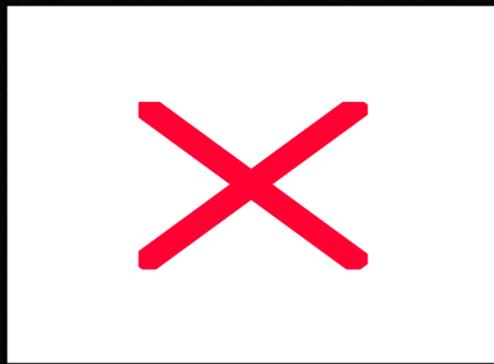

Different Strokes....

site of 13
INO
we can
that different
the Sun have
signatures:

AR TTs are
“compressed”
QS TTs are “normal”
CH TTs are “stretched”

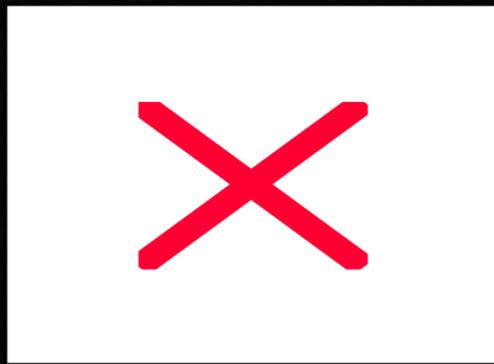

Question One:

If the travel-time from a coronal hole region is significantly different from a region of QS then....Is there a chromospheric footprint of the Solar Wind?

Or.....

Can we correlate chromospheric structure with insitu measurements of the solar wind?

Connecting to 1 AU

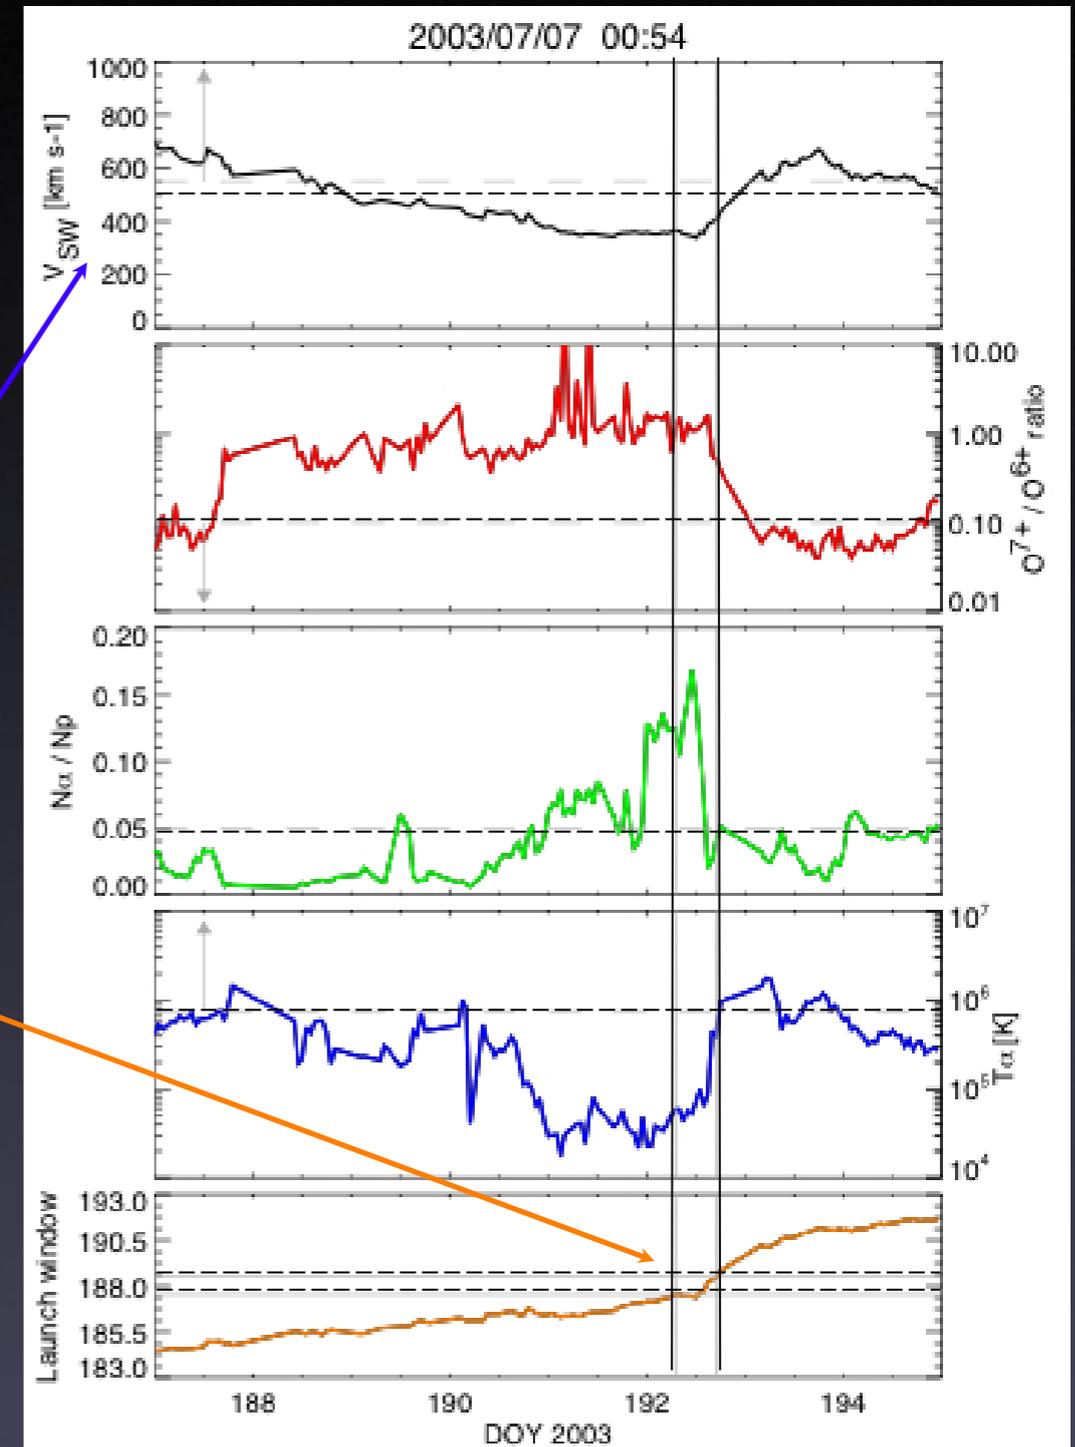

Use One Hour ACE data

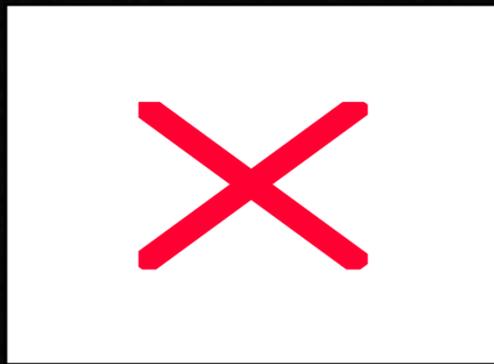

Compute “ballistic” travel time of parcel from V_{sw} at observing time.
($T_b = 149 \times 10^6 \text{ km} / V_{sw}$)

Account for Solar Rotation (if necessary)

Find “launch window” for parcel

Correlate mean in situ variables with Δz

V_{sw} & Composition Correlations

All power law fits:

$$Y = A * (\Delta z)^B + C$$

V_{sw} :

$$A = (1.49 \pm 0.19) \times 10^{-5}$$

$$B = 4.56 \pm 0.33$$

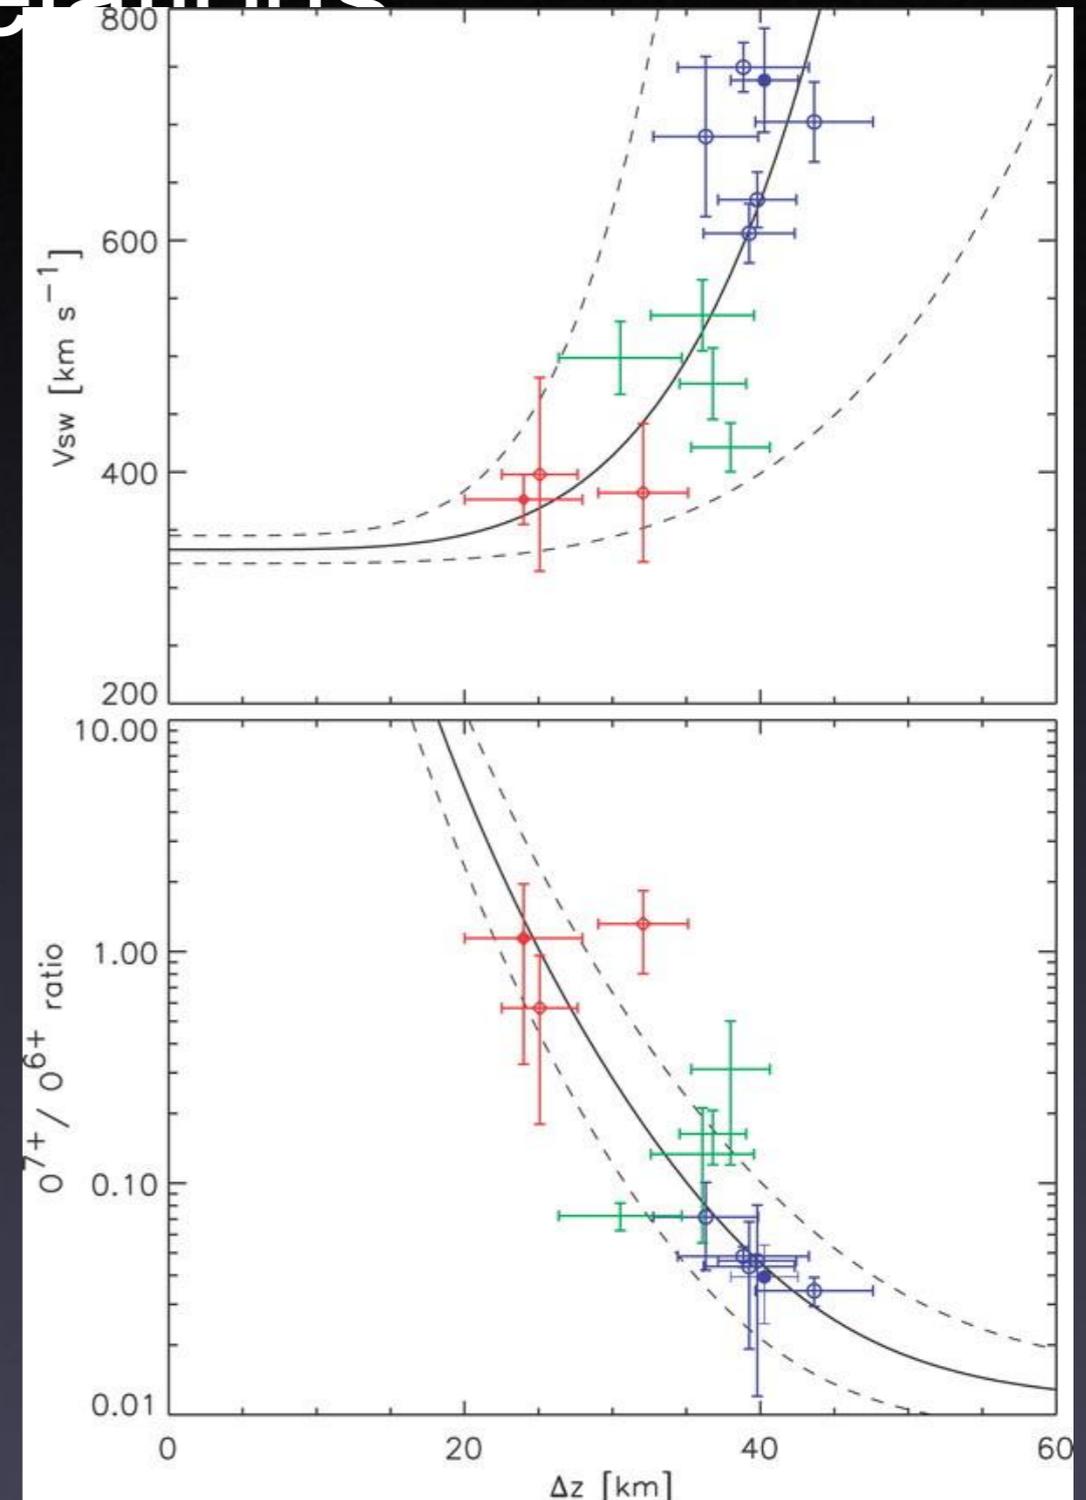

$$C = 333 \pm 12$$

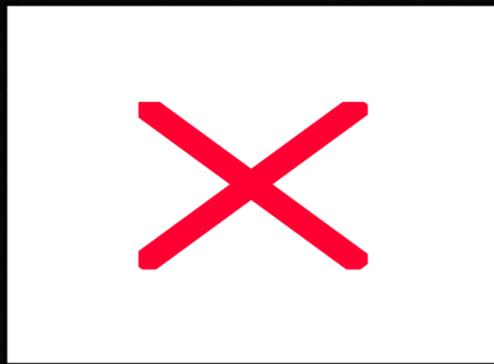

O^{7+}/O^{6+} :

$$A = (1.22 \pm 0.11) \times 10^{10}$$

$$B = -7.21 \pm 0.23$$

$$C = 0.011 \pm 0.003$$

Chromosphere-Solar Wind Correlations

*plots later if time permits

Spearman rank-order correlation coefficients between Chromospheric structure and in situ observations

O^{7+}/O^{6+}	-0.909		
V_{sw}	0.736	N_{alpha}/N_p	-0.682
T_{proton}	0.864	N_{proton}	0.109
T_{alpha}	0.818	β	0.064
V_{rms}	0.727	T_{α}/T_p	0.209

McIntosh & Leamon, 2005, GRL, In Prep.

Results & Implications

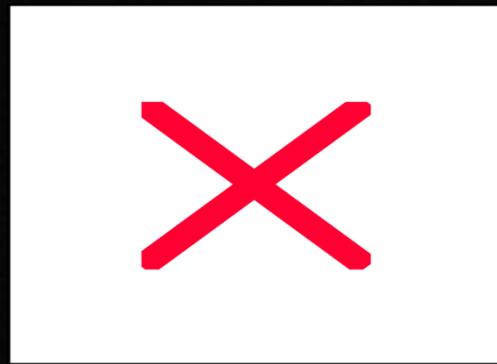

Regions where separation is small correspond to regions of slow, hot solar wind. The atmosphere is “compressed” in and around active regions.

Intermediate values largely correspond to quiet Sun regions and give intermediate values of speed and temperature.

Regions where separation is large correspond to regions of fast, cool solar wind. It appears as though the atmosphere is “stretched thin”. These are coronal holes.

Consistent with the “solar wind scaling law” of Schwadron & McComas (2003, ApJ, 599, 1395). Not to mention earlier work (Leer & Holzer 1979).

Appears to provide an analog diagnostic to “dial in” solar wind parameters from on-disk observations. Implies, **a predictive capability?**

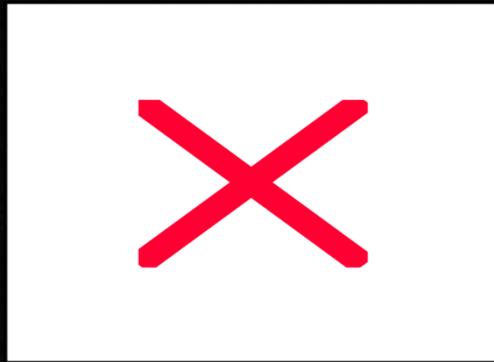

Conclusions

Timeseries observations of the chromosphere....

Provide diagnostics of wave properties and the magnetic environment through which they propagate.

Point to a connection between the chromospheric plasma, its structure and the speed and composition of the solar wind measured in situ.

It is, as yet, unclear why the chromosphere should care about the magnetic topology above is “open” or “closed” to the heliosphere above.

Future Efforts

Theoretical / Analysis / Modeling Investigations

- Investigate the predictive capability of chromospheric structure
- Identify and Study “events” in MOTH data to study signature & timing
- Developing a clearer picture of wave/field interaction in the chromosphere
- Low-Frequency energy flux in magnetic network

Observational Investigations

TRACE's end time is nigh!

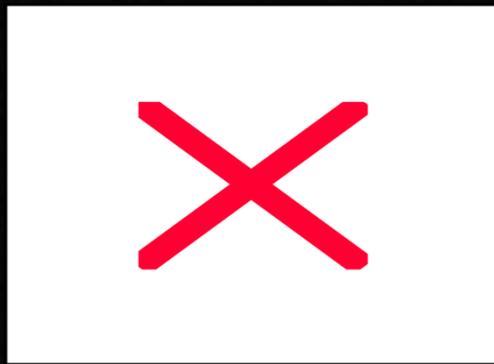

- Get more observations of varied chromospheric topographies

MOTH II Deployment Austral Summer 2005/6

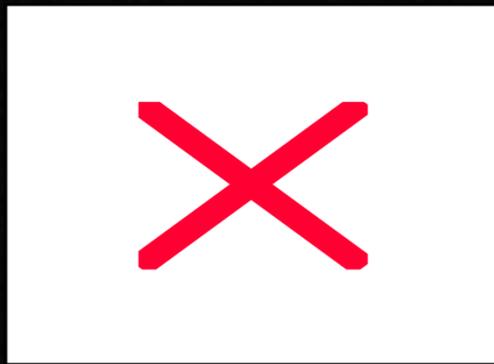

- Doppler Observations at multiple (five) heights are key
- Coordination with TRACE/SOHO

Rapid Acquisition Imaging Spectrograph (RAISE) Sub-Orbital Sounding Rocket Observations - Summer 2006

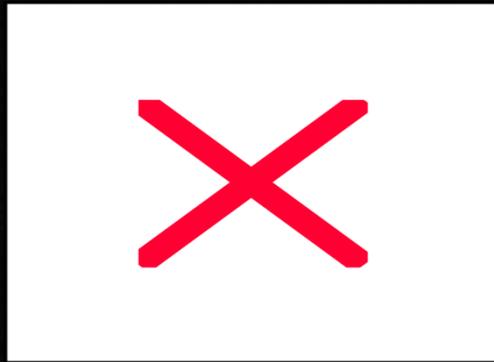

- 10Hz 1600Å imaging, Ly-alpha, Si II, C IV, Ne VIII 1Hz raster spectra

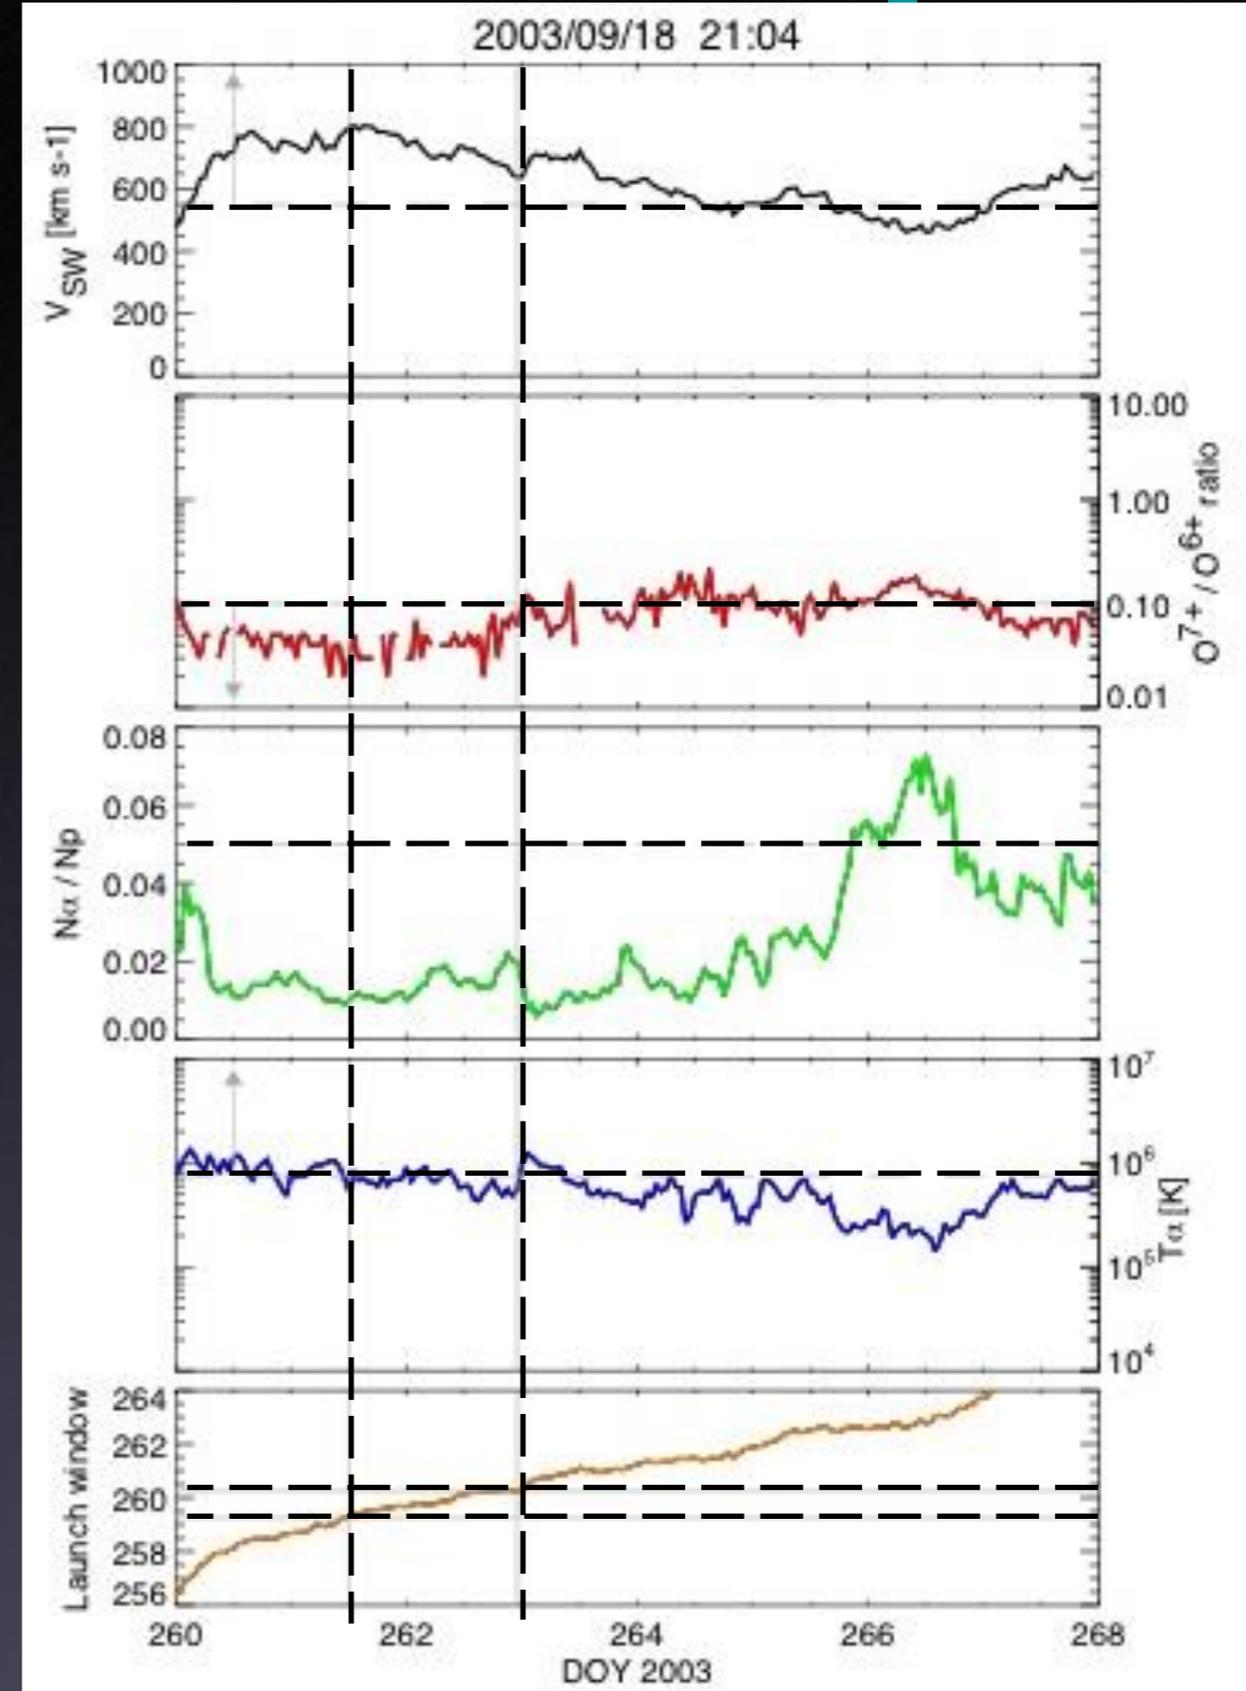

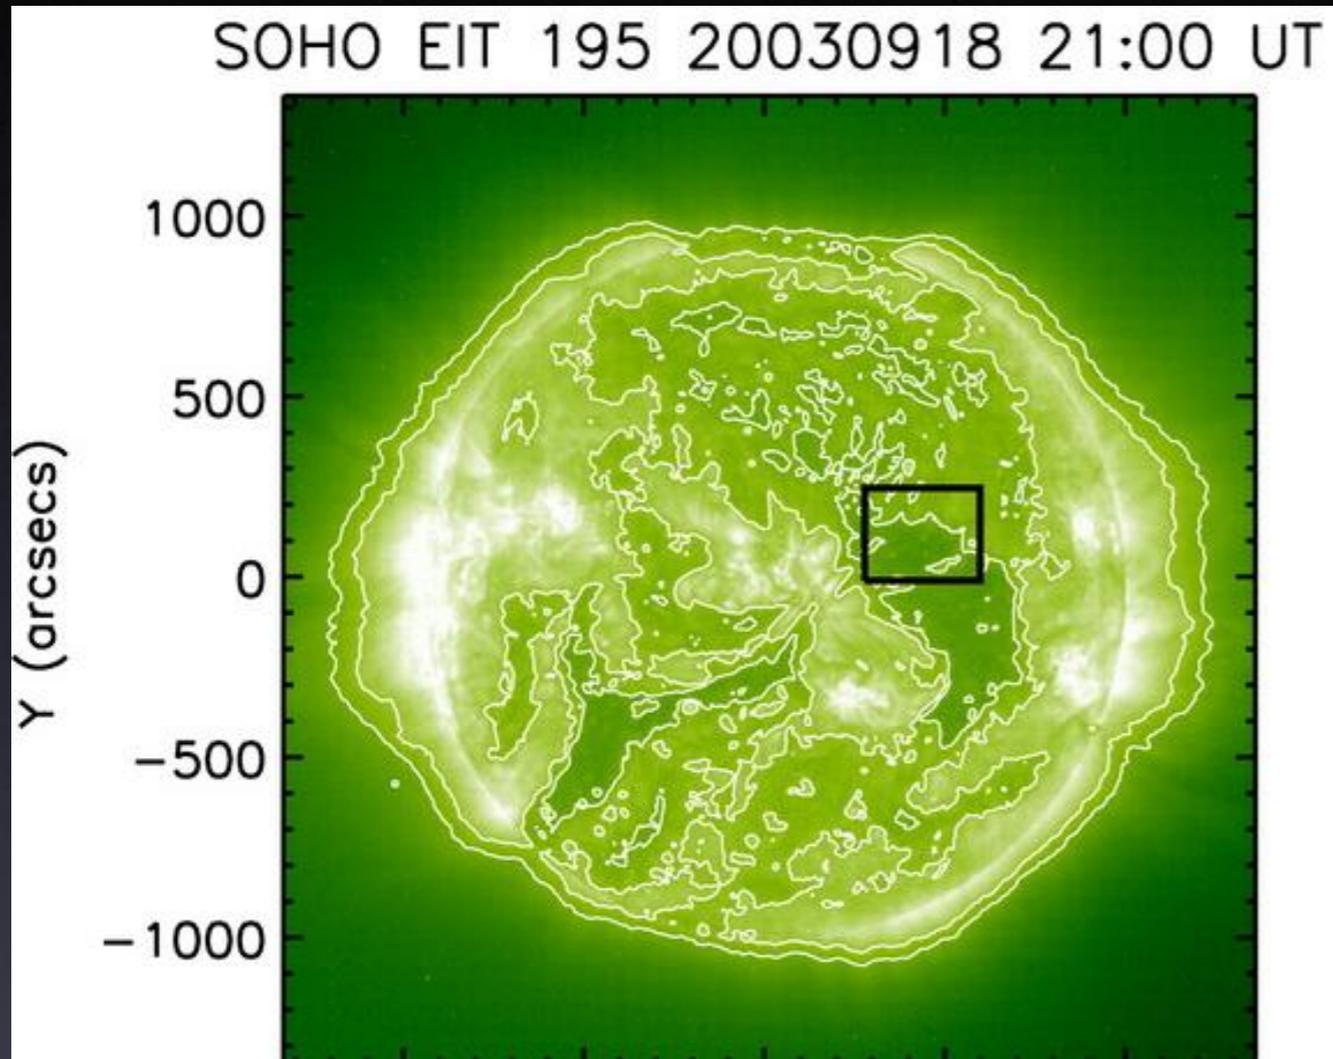

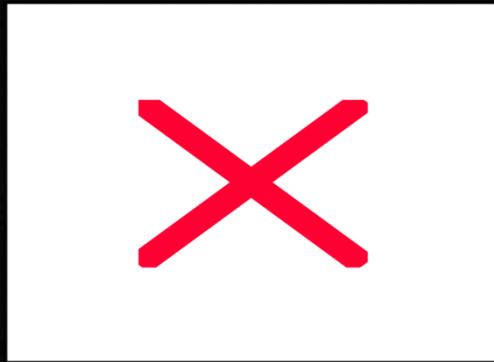

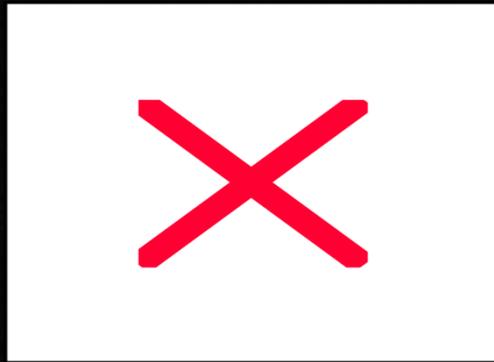

Extra Slides

We discuss new results derived from timeseries observations of the solar chromosphere by the TRACE spacecraft and the MOTH experiment on the South Pole Solar Observatory. Inferred diagnostics of the chromospheric wave field near the "magnetic transition region" are indicating that changes in the chromospheric plasma reflect properties of eruptive processes readily observed in the EUV corona and properties of the nascent solar wind measured in situ. We discuss the implications of these efforts and look to near future capabilities.

SOHO EIT 195 20030707 00:48 UT

Alpha & Proton Temperatures

$T_{\alpha\lambda\pi\eta\alpha}$

$$A = (8.07 \pm 4.36) \times 10^{-4}$$

$$B = 5.60 \pm 0.17$$

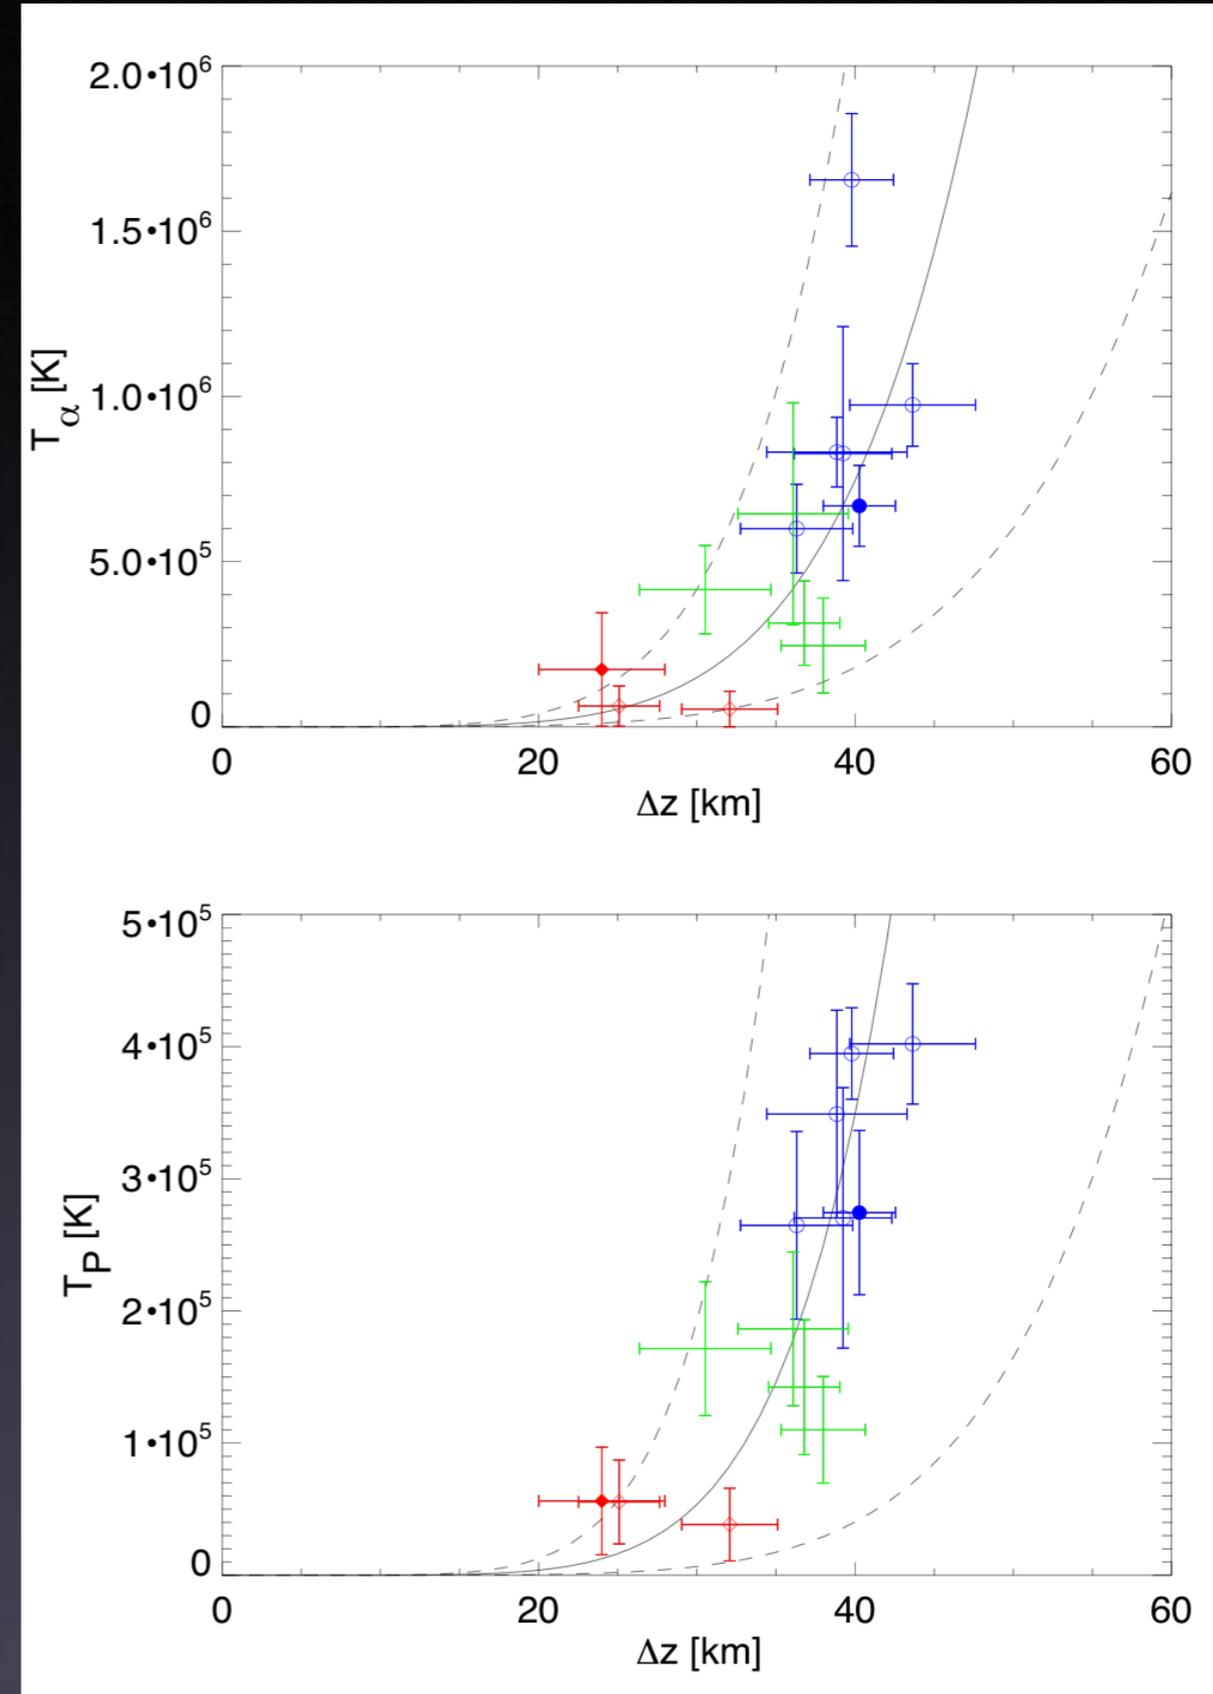

$$C = 8.11 \pm 7.77$$

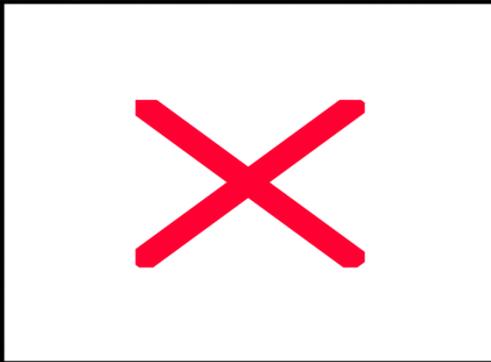

T_p

$$A = (1.23 \pm 0.92) \times 10^{-5}$$

$$B = 6.42 \pm 0.24$$

$$C = 43 \pm 3$$

Alpha & Proton Numbers

$N_{\alpha\lambda\pi\eta\alpha} / N_p$:

$$A = (8.07 \pm 4.36) \times 10^{-4}$$

$$B = 5.60 \pm 0.17$$

$$C = 8.11 \pm 7.77$$

V_{rms} :

strong correlation on data points; large error bars. Not fitted, but shown for the interested...
